

# SpaceCharge Calibration into the future and demands on the trigger, now.

We think of our events like this ...

Data Taken June 25, 2000.

Most of our events look more like this ...

# SpaceCharge from the events cause distortions

- Beam gas and other up stream events
  - not synchronous with our trigger
  - Scales with beam intensity (*not Luminosity*)
- The collisions at STAR
  - synchronous with out trigger
  - Scales with Luminosity
- In the future, the average Luminosity will go up a factor of 40 but the beam intensity will only go up a factor of 2 to 4 !
  - We have to prepare for a significant increase in space charge due to the collisions in the detector.
  - We have to be able to distinguish the two sources of distortion

We have to be able to distinguish the two sources of distortion

# Model for the distortions

- **Old Model**

- Beam gas events leave a uniform deposition of charge in the TPC
- The charge from the events is not significant

- **New Model**

- Beam gas events leave a  $1/R^{**2}$  distribution of charge in the TPC
- The charge from the events is not significant in the 2001 data, but in the future (including this year) ???

# Uniform .vs. $1/R^2$ Space Charge Distribution

Radial Distortions

# A Wide Range of Distributions

$1/R^3$

$1/R^2$

Wieman's Hifet

$1/R$

Linear 2:1

Linear

These (and other) Distributions are Available in StMagUtilities

# DCA, Steering at the RICH, and $\Delta p$

- The RICH Scaler has an arbitrary normalization
- The DCA's have been tuned to be the same in both cases
- $\Delta p$  is different by a factor of 2
- Steering at the Rich changes sign under these conditions

## 2 Equations, 2 Unknowns

- We can simultaneously fit the DCAs and match the steering at the RICH due to the beam gas induced space charge
  - Choose the right charge distribution  $1/R$ ,  $1/R^2$ ,  $1/R^3$ , etc.
  - Choose the RICH scaler normalization constant

- SpaceCharge corrections are significant today
  - And at  $40x < \mathcal{L} >$
- Tools are available to calculate the corrections
  - Two sources of spacecharge
- We need scalers and diagnostics for each source of charge
  - Monitor  $\mathcal{L}$
  - Monitor beam current
- The RICH Mult Scaler is gone
  - We need a replacement
    - Record all events where CTB hits exceed 16
    - This is a job for the trigger group
- We need to track the beam current and/or the distribution of charge in the TPC for untriggered events.
  - Ideas?
- Recent progress with the laser cluster finder means we will be taking laser data during the runs.

# Contingency Trigger Plan Needed

- RHIC ran protons last year and so they can do it again
  - The proton run is a shoe-in
  - But it is contingent on achieving 40%(?) polarization at the source
- There is a small probability that the machine folks can't run a deuteron beam
  - Source to AGS transport problems
  - RHIC tuning issues (first attempt at asymmetric beams)
  - neutron background
- If the machine folks are forced to punt on either issue, then there will be a mad rush to run a different beam
  - The exact choice of beams will be a long messy conversation, on short notice, in a smoke filled room.
- We need a contingency trigger plan for symmetric heavy ions
  - Running at higher multiplicity than either p-p or d-Au
